A NEW HOST FOR JALYSUS SPINOSUS
(HETEROPTERA: BERYTIDAE)
AND NEW HOST FAMILY (COMMELINACEAE)
FOR STILT BUGS

A. G. Wheeler, Jr.

ABSTRACT: Nymphs of the stilt bug Jalysus spinosus were observed on the densely pubescent Tradescantia hirsuticaulis on Glassy Mountain in South Carolina, but they were absent from coexisting colonies of the glabrous T. ohiensis. This host association supports the characterization of metacanthine berytids as specialists on glandular-hairy plants. Tradescantia hirsuticaulis is the first member of the spiderwort family, Commelinaceae, known to serve as a berytid host.

Four species of the stilt bug genus Jalysus Štål occur in North America: J. caducus (Distant), known in the United States only from Arizona and Texas; J. balli Harris, a Mexican species recorded from Arizona; and the more wide-ranging J. spinosus (Say) and J. wickhami Van Duzee (Froeschner and Henry 1988, Henry and Froeschner 1992). Following its original description (Van Duzee 1906), J. wickhami was reduced to a variety of J. spinosus (Van Duzee 1914) but was reinstated as a full species by Harris (1941).

Until recently, J. spinosus was assumed to be the most commonly collected and most widely distributed of these berytid species. Because J. wickhami was described from Arizona and California, early workers apparently assumed it was a western species. It has been shown, however, that J. wickhami occurs in southern Canada and throughout the United States and also extends into Mexico. In contrast, J. spinosus is generally restricted to southern Canada and the United States east of the 100th meridian (Wheeler and Henry 1981, Scudder 1991).

It has also been demonstrated that the Jalysus species used in nearly all biological studies in North America has been misidentified. Jalysus wickhami – not J. spinosus – is an occasional pest of tomato. It is also the species whose life history has been studied on onagraceous plants, and is the natural enemy augmentatively released in the southern states to help control aphids and lepidopteran pests of tobacco (Wheeler and Henry 1981 and references therein).

Whereas the polyphagous J. wickhami uses diverse hosts, particularly glandular-hairy dicots of the Malvaceae, Onagraceae, Oxalidaceae, Scrophulariaceae, and Solanaceae, J. spinosus has a much narrower host range — mostly monocots. Its primary hosts appear to be grasses of the genus Panicum, although nymphaal development also occurs on a few dicots, namely the ona-

**STUDY SITE AND HOST PLANTS**

Glassy Mountain Heritage Preserve is a natural area northeast of Pickens, South Carolina (Pickens Co.). Managed by the state's Wildlife and Marine Resources Department, Glassy Mountain is a 26-ha, relatively undisturbed monadnock or isolated mountain that has withstood the forces of natural erosion in the piedmont. This granitic dome (elev. 518 m) is similar in appearance to the nearby Table Rock Mountain and structurally similar to Georgia's Stone Mountain, probably the best-known monadnock in the southeastern United States (Nelson 1988).

The berytid host *T. hirsuticaulis*, a rather uncommon member of the spiderwort family Commelinaceae, is found in dry woods and rock outcrops from North Carolina to Florida and in Arkansas and Texas. This spiderwort species is characterized by hirsute stems and generally pubescent leaves (Rickett 1967, Radford et al. 1968). On Glassy Mountain, it grows on several rock outcrops near the summit. Observations on *J. spinosus* were made in colonies of *T. hirsuticaulis* that were growing with *T. ohiensis* Raf. southeast of the promontory near the forest tower. Voucher specimens of this berytid have been deposited in the collection of the National Museum of Natural History, Washington, D. C.; host plants have been deposited in the A. C. Moore Herbarium, University of South Carolina, Columbia.

**HOSTS OF JALYSUS SPINOSUS**

On 4 May 1991, adults of *J. spinosus*, including mating pairs, were common on *T. hirsuticaulis*, which was in full bloom. This berytid overwinters in the adult stage (Wheeler and Stimmel 1988), and nymphs were not yet present. No *J. spinosus* adults were collected in early May from the essentially glabrous *T. ohiensis*, even though its colonies coexisted with those of *T. hirsuticaulis*.

In 1993, nymphs were abundant on 30 May on *T. hirsuticaulis* that had finished blooming. First through fourth instars and one adult were observed on fruits, pedicels, and other plant parts. As in 1991, no life stages could be found on *T. ohiensis*, including colonies in which stems of the two species were touching. Nymphs and adults were also present on the rock outcrop on the panic-grasses *Panicum sphaerocarpon* Elliott and *P. laxiflorum* Lam.
DISCUSSION

Metacanthine berytids, including Jalysus species, develop mainly on well-glanded, pubescent hosts, feeding preferentially on glandular hairs or on arthropods entrapped by plant secretions. Such use of glandular-hairy plants, although atypical among heteropterans, is also characteristic of many dicyniphine mirids (Wheeler and Schaefer 1982 and references therein). The use of T. hirsuticaulis as a host of J. spinosus on Glassy Mountain, and its apparent absence from the glabrous T. ohiensis, is consistent with previous biological studies of this berytid genus. T. hirsuticaulis becomes the only non-poaceous monocot known as a host of this stilt bug and the first member of the family Commelinaceae (and order Commelinales) recorded as a berytid host plant.

ACKNOWLEDGMENTS

I am grateful to S. H. Bennett and J. A. Sorrow (South Carolina Wildlife & Marine Resources Dept.) for permission to collect insects at Glassy Mountain Heritage Preserve. J. B. Nelson (Dept. of Biological Sciences, University of South Carolina) for plant identifications, and T. J. Henry (Systematic Entomology Laboratory, USDA, c/o U. S. National Museum) and E. R. Hoebeke (Dept. of Entomology, Cornell University) for reviewing the manuscript.
